## Summary

Birds are suffering from steep population declines on a global scale and they are one of the few taxonomic groups for which these declines are well documented by long-term monitoring data. This study provides a synthesis of the status of the breeding birds of Greece. To this aim, we retrieved population size estimates from six sources spanning 22 years (1992–2014) and calculated species' trends in Greece. Using the IUCN Red List assessments for each species we assessed whether ecological traits including habitat and diet preferences were associated with species' trends and conservation status in Europe and determined major threats affecting birds in Greece. Moreover, we assessed the importance of Important Bird & Biodiversity Areas (IBAs) in terms of declining trigger species. Results showed that almost one fifth of the breeding birds in Greece have declining populations. Raptors were found to be the most threatened group of birds whereas the highest declines by dietary group were observed in scavengers, with 60% of species showing a decreasing trend. The most common threats were those that cause habitat alteration and degradation as well as more direct effects such as poisoning. Our results suggest that restoration of habitat and ecosystem functions along with the management of protected areas and improvement of legislation should be the main conservation actions undertaken and pinpointed the IBAs where they should be prioritized for implementation. Finally, further research, especially on specific drivers of population change, along with further examination of current and past population trends, will increase the power and accuracy of future regional Red List assessments especially concerning the breeding species for which the country bears the greatest responsibility.

**Keywords:** bird population trends, conservation priorities, Greece, Important Bird and Biodiversity Areas, IUCN Red List

## Introduction

Global biodiversity is decreasing at alarming rates (Barnosky *et al.* 2011, Ceballos *et al.* 2017). As a result of environmental degradation, habitat loss, invasive species and effects of climate change, more and more species are threatened with extinction (Butchart *et al.* 2010). Thus, the urgent need to reduce the rates of biodiversity loss has been recognized as a priority environmental concern, resulting in a number of international conventions and agreements. Towards that goal, the International Union for the Conservation of Nature (IUCN) Red List of Threatened Species is undoubtedly the most comprehensive and updated source regarding the global conservation status of animals and plants, highlighting species with the greatest extinction risk, assessing threats and promoting their conservation through management actions and research recommendations (Rodrigues *et al.* 2006).

Birds are well-known to be suffering steep population declines on a global scale (Butchart *et al.* 2004, Rosenberg *et al.* 2019) that could in turn disrupt critical ecosystem services (Şekercioğlu *et al.* 2004). Birds are excellent indicators of terrestrial and aquatic biodiversity, habitat quality and environmental conditions, and can be used to assess conservation targets (Kati *et al.* 2004, Mace and Baillie 2007). Their usefulness and reliability as ecological indicators lies mainly in the fact that they are a very widespread and diverse taxonomic group, their ecology is very well-documented with long-term monitoring efforts held in several countries, and since they are usually top predators, they are sensitive to climate and land use changes (e.g. Gregory *et al.* 2005). For instance, estimating bird trends is key for setting bird conservation priorities (Sutherland *et al.* 2004), whereas bird trends often reflect population changes in other animal and plant taxa thus providing a better understanding of wider environmental health (e.g. Gregory *et al.* 2005).

Greece holds an important geographical position, located at the intersection of three continents, Europe, Africa and Asia. In total, 455 bird species have been recorded in Greece, of which 347 species occur regularly (Legakis and Maragou 2009). The country has no endemic species but encompasses the southernmost or westernmost limit of several species' breeding range within the Western Palearctic (Legakis and Maragou 2009). Two species, the Goosander *Mergus merganser* and the Greylag Goose *Anser anser*, exhibit isolated breeding populations that are considered to be relict populations that settled in the area after the last glacial maximum (Catsadorakis *et al.* 2016, Bounas *et al.* 2018). Moreover, for some species, Greece hosts a major percentage of their global population, e.g. Eleonora's Falcon *Falco eleonora*, with more than 80% of its global population breeding in Greece (Dimalexis *et al.* 2008).

In the last few decades, ornithology in Greece has undoubtedly flourished, with several studies conducted which mainly dealt with monitoring surveys, bird conservation biology, reproductive biology, habitat use and diet of birds (Kazantzidis 2007), therefore significantly contributing to our current understanding of distribution, numbers and species' ecology. Naturally, increased research and knowledge has led to the implementation of conservation measures for certain threatened species. Several conservation projects have been implemented in the country so far, mainly under the framework of European Commission's LIFE programme, the main funding instrument for nature conservation in the European Union. From its launch in 1992, a total of 81 LIFE Nature projects have been implemented in Greece with 28 of them focused specifically on birds (<https://ec.europa.eu/environment/life/project/Projects/index.cfm>, accessed on July 2020). Despite all of the abovementioned efforts, there is currently no comprehensive review of the trends, status, threats, and conservation needs of all the bird species breeding in Greece. The main aim of this study is to provide a synthesis of the status of the 246 breeding birds of Greece by compiling available published information including population estimates and IUCN assessments. Thus, we assess the extent of increase or decline for each species and determine whether ecological traits including habitat and dietary preferences are associated with species' trends and conservation status. We also evaluate which Important Bird & Biodiversity Areas (IBAs) designated in Greece hold the highest number of species and which of these IBAs face the greatest threats. Finally, we determine the threats affecting most of the breeding species in Greece and identify priority actions for conservation and research. Our findings will be a first step towards an integrated approach in setting conservation priorities in a national level.

## Methods

### Data collection

To compile a contemporary list of the breeding birds of Greece we included 242 of the 244 species that have been reported to have a permanent and regular breeding population in Greece in the late 1990s (Handrinos and Akriotis 1997). The two species excluded were the Red-legged Partridge *Alectoris rufa*, as the fate of this introduced population is unknown, and Marmora's Warbler *Sylvia sarda* since previous records in the 1980s are probably a result of misidentification (Handrinos and Akriotis 1997). We also did not consider the Black Francolin *Francolinus francolinus*, since it has become extinct in the country since the second half of the 19<sup>th</sup> century (Handrinos and Akriotis 1997). Additionally, four more species, the Short-eared Owl *Asio flammeus*, Great Bittern *Botaurus stellaris*, Cattle Egret *Bubulcus ibis* and Rook *Corvus frugilegus* were included as breeding species. More specifically, the Short-eared Owl and the Great Bittern were listed as breeding in the most recent Red Data Book of the Threatened Animals of Greece (Legakis and Maragou 2009), while the Cattle Egret and Rook, although irregular breeders in the past, now breed regularly in the country (Kazantzidis *et al.* 2016). Consequently, we focused on a list of 246 species breeding in Greece.

Population size estimates for all breeding species in Greece were retrieved from six sources spanning 22 years, from 1992 to 2014: i) The first regional Red Data Book of Greece (Karandinos and Paraschi 1992), before the establishment of the modern criteria and categories by IUCN. This is the first publication that estimated extinction risks for the birds of Greece and provided population size data on 48 breeding species, mainly non-passerines. ii) The first ever review of the status and populations of all wild species of birds in Europe at a country level (Tucker and Heath 1994), including 108 breeding species from Greece. We did not include data for 34 of these species for which the population estimates were based on poorly known or no quantitative data. iii) 'The birds of Greece' (Handrinos and Akriotis 1997), the first, and up to now the only complete publication on the status of all bird species of Greece. We extracted population data for all the breeding species of Greece. iv) The 'Birds in Europe 2' publication (BirdLife International 2004) that updated the previous version from 1994 and included quantitative data for all species and countries of Europe. Data for all 246 breeding species of Greece were extracted. v) The second regional Red Data Book of Greece (Legakis and Maragou 2009) although the first one using the quantitative criteria of IUCN. In total, 122 species have been assessed and assigned to extinction risk categories, and for 64 of them detailed population data were included. vi) The most recent publication on the status of European birds (BirdLife International 2017) that updated the 2004 publication. Even though it was published in 2017, the majority of the data on population estimates refers to 2013–2014, since they were collated for the publication of European Red List of Birds (BirdLife International 2015). This publication contained population data for 85 breeding species Greece. However, estimates for all 246 breeding species were kindly provided by the Hellenic Ornithological Society/BirdLife Greece for the purposes of this study. Our final dataset, therefore, included population size estimates (as minimum and maximum values) for all 246 breeding species, with 225 of them assessed for at least three distinct points in time (1992, 1994, 1997, 2004, 2009 and 2014; Table S1 in the online supplementary material).

The retrieved population estimates do not come from a single standardized method; therefore, such heterogeneous datasets could provide misleading rates of change for certain species. Both for decreasing and even more so for increasing species, it is challenging in some cases to clarify whether the trend is due to actual changes in abundance (due to successful conservation measures for example) or a change in the method of estimation, or even due to increased survey effort in known or new areas of occurrence (Brouwer *et al.* 2003, Dimalexis *et al.* 2008). Thus, overall patterns should be viewed with some degree of caution.

Each one of the species breeding in Greece was assigned to a taxonomic order, to its population trend in Europe (Increasing, Stable, Decreasing, Unknown) and to the IUCN category of extinction

risk according to BirdLife International (2015). Red List assessments also contain ecological information such as habitat preferences. These are coded against a hierarchical habitat classification scheme, with broad (Level One) habitat types that further include more specific (Level Two) habitats. For each species, we considered classifications that were coded by IUCN as of Major Importance, indicating that the habitat type is an absolute requirement, hereafter as primary habitat (<https://www.iucnredlist.org/resources/habitat-classification-scheme>). Furthermore, we classified all species into dietary groups, hereafter 'primary diet', based on data from Wilman *et al.* (2014) quantifying the dietary contribution of 10 different food categories. Species were assigned a primary diet when they obtained the majority of their resources (>60%) from one of the corresponding food categories while the remaining species were classified as omnivores (Pigot *et al.* 2016). Similar to habitat preferences, IUCN Red List assessments classify threats, recommended conservation actions and research needs hierarchically with Level One, encompassing Level Two classifications (Salafsky *et al.* 2008). In each species, we assigned the corresponding threats at Level One except for 'Biological Resource Use' and 'Natural Systems Modifications', which were assigned at Level Two of the classification scheme following McClure *et al.* (2018), since these broad (Level One) categories represent heterogeneous threat types. We only considered threats coded as having a Low, Medium, and High impact. Recommended conservation actions were assigned at Level One whereas research needs were assigned at Level Two for each species. Finally, we retrieved any breeding bird of Greece that qualifies as an IBA Trigger species, under the relevant criteria (BirdLife International 2014), in any of the 204 IBAs identified in Greece (Portolou *et al.* 2009, Fric *et al.* 2012).

### Data analysis

The population trend of each species in Greece was identified by calculating the slope of the least squares regression line between the year and the respective mean population size (mean of minimum and maximum estimates). For the results to be comparable in magnitude among species we standardized the mean population estimates (z-transformation) resulting in standardized slopes (Schielzeth 2010). Standardized slopes were subsequently projected to biologically meaningful values reflecting the percentage rate of change of species' populations per year (Kleinbaum *et al.* 2013, Sauer *et al.* 2017). Species with positive or negative slopes showing an overall annual rate of change > 1% were assigned to an 'Increasing' or 'Decreasing' trend respectively. Species with either a slope point estimate of zero or an overall annual rate of change < 1% were characterized as 'Stable' (van Strien *et al.* 2001, Vorisek *et al.* 2008). Species for which population size estimates were not available for at least two points in time, were considered as 'Unknown' trend. Additionally, we calculated the percentage change between the oldest and the most recent population size estimate for each species across years to evaluate the overall largest population increases and declines.

Furthermore, we calculated the percentage of species per taxonomic order and per ecological trait (habitat used, primary diet) within each Red List category and for each direction of population trend both in Greece and in Europe. We performed chi-square tests to examine any statistically significant differences in numbers of threatened or declining species within groups. To determine the threats affecting the declining breeding birds in Greece and identify priority actions for conservation and research we calculated the number of species for which each threat type was listed as well as the number of species with decreasing trends for which each category of conservation action and research needed was recommended by IUCN. Finally, we examined the importance of IBAs for the breeding birds of Greece by calculating the richness of trigger species, and the number of declining trigger species in each IBA. All data manipulation and analyses were performed in R 3.6.2 (R Core Team 2019) and QGIS 2.18 (QGIS Core Team 2016).

### Results

Of the 246 breeding birds of Greece analyzed, 110 species (44.7%) had positive trends, 87 species (35.4%) had stable trends and 46 species (18.7%) were found to be declining. Three species (1.2%;

Table 1. Top ten species with the greatest changes in their population sizes in Greece along with their European trend and the European IUCN category of extinction risk. Values are presented as percentage change from the oldest to the newest population size estimate (1992 to 2014).

Black-headed Gull *Larus ridibundus*, Eurasian Pygmy-owl *Glaucidium passerinum* and the Wood Warbler *Phylloscopus sibilatrix*) were assigned an unknown trend. Extreme population declines were observed for the Whiskered Tern *Chlidonias hybrida* and the Egyptian Vulture *Neophron percnopterus* with an overall loss of 97.5% and 95.2% of their populations respectively between 1992 and 2014. The Imperial Eagle *Aquila heliaca* and Purple Heron *Ardea purpurea* also showed declines of great magnitude with values of 95% and 90% respectively. Top increasers include Rook *Corvus frugilegus* (99.9%), Common Starling *Sturnus vulgaris* (98.6%), Mute Swan *Cygnus olor* (98%) and Cattle Egret *Bubulcus ibis* (97.5%). The top 10 species with the largest population change in Greece are shown in Table 1. Species showing the highest average annual decline rates during 1992–2014 include the Whiskered Tern (5.1%), Moustached *Acrocephalus melanopogon* and Great Reed *Acrocephalus arundinaceus* Warblers (4.7% and 4.3% respectively), and Egyptian Vulture (3.9%). On the other hand, the highest average annual increase rates were observed in Collared Dove *Streptopelia decaocto* (9.6%) and Pallid Swift *Apus pallidus* (8.7%). The 10 species with the highest rate of increase and decrease in Greece are shown in Table 2. Eight species (3.3%) of the 246 breeding birds of Greece assessed by IUCN, are considered threatened in Europe ('Vulnerable' or 'Endangered') with four more species (1.6%) classified as 'Near Threatened'. A quarter of the 246 species ( $n = 63$ , 25.6%) have declining population trends in Europe, another quarter ( $n = 62$ , 25.2%) show increasing population trends, whereas for 75 species (30.5%) trends are stable and for the remaining 46 species (18.7%) the trends are unknown. A comparison of the proportion of threatened or declining species (based on their trend both in Greece and Europe) between taxonomic orders (Figure S1), showed no disproportionate declines in Greece (Chi-squared = 62.6,  $df = 51$ ,  $P = 0.13$ ) or in Europe (Chi-squared = 74.1,  $df = 51$ ,  $P = 0.09$ ). However, 11.5% of the breeding raptors of Greece (Accipitriformes, Falconiformes) are found to be threatened (Chi-squared = 87.9,  $df = 51$ ,  $P = 0.001$ ).

Table 2. Top ten species with the highest increase and decrease in their population sizes in Greece along with their European trend and the European IUCN category of extinction risk. Values are presented as percent rate of change per year for years 1992 to 2014.

Species	% rate of change in Greece (per year)	European trend	IUCN Europe
<b>Decreasing</b>			
<i>Chlidonias hybrida</i>	-5.1	Increasing	LC
<i>Fringilla coelebs</i>	-4.7	Stable	LC
<i>Acrocephalus melanopogon</i>	-4.3	Unknown	LC
<i>Acrocephalus arundinaceus</i>	-4.1	Unknown	LC
<i>Neophron percnopterus</i>	-3.9	Decreasing	EN
<i>Regulus regulus</i>	-3.8	Decreasing	LC

<i>Sitta krueperi</i>	6.0	Decreasing	LC
<i>Passer montanus</i>	5.8	Uncertain	LC

Regarding ecological traits, and specifically habitat preferences (Figure S2), 152 of the 246 species breeding in Greece (61.8%), require at least one broad habitat type (i.e. primary habitat). The Level One habitat type 'Forest' was the most frequent habitat type, listed as a primary habitat for 53 (34.9%) species. Of these forest birds, 30.2% show a declining trend in the country, 41.5% are stable and 24.5% of them are increasing. Habitat type 'Wetland' was required by 31 species (20.4%), with most of them showing an increasing trend (48.4%), whereas a 25.8% of wetland species showed a stable and another 25.8% showed a decreasing trend. Of the 16 species (10.5%) that require the habitat type 'Shrubland', most are either declining (37.5%) or stable (37.5%), with the remaining 25% exhibiting an increasing trend. Proportionally, there were no differences between species that require a specific habitat type and the trend direction, in Greece (Chi-squared = 41.3, df = 30,  $P = 0.08$ ) or in Europe (Chi-squared = 32.2, df = 30,  $P = 0.36$ ). There were no differences between the proportion of species assigned to a European Red List category concerning their primary habitat (Chi-squared = 13.8, df = 10,  $P = 0.18$ ). For the majority of species breeding in Greece ( $n = 110$ , 44.7%), invertebrates were the primary type of resource in their diets, followed by omnivores ( $n = 46$ , 18.7%) and plant/seed eaters ( $n = 39$ , 15.9%). The highest declines by dietary group were observed in scavengers, with three out of five species (60%) showing a decreasing trend in Greece (Figure 1). Proportionally, scavengers are indeed more likely to be in decline in Greece than species having other primary types of diet (Chi-squared = 26.6, df = 15,  $P = 0.03$ ) although this does not seem to be the case in Europe (Chi-squared = 18.9, df = 15,  $P = 0.22$ ). In addition, scavengers are more likely to be threatened (Chi-squared = 49.1, df = 15,  $P < 0.001$ ), as this was the only dietary group where 40% of species are assigned to an IUCN threatened category.

The most common threat identified for birds breeding in Greece was 'Agriculture' ( $n = 114$ , 46.3%), coded as having low impact for 45 species (39.5%) and medium/high impact for 69 (60.5%). 'Hunting and collecting' threatens 88 (35.8%) species, having low impact and medium/high impact on 60 (68.2%) and 28 (31.8%) species, respectively. 'Pollution' is listed as a threat for the third largest number of species in Greece ( $n = 82$ , 33.3%), impacting 49 of them

Figure 1. Percentages of species exhibiting different directions of population trends (Increasing, Decreasing, Stable, Unknown) in a) Greece and b) in Europe, and c) within different European IUCN Red List Categories (Endangered (EN), Vulnerable (VU), Near Threatened (NT) and Least Concern (LC)), for each dietary group. Number of species in each group is shown in brackets.

(59.8%) on a low scale and 33 (40.2%) on a medium/high scale (Figure 2). For the 46 species with a decreasing trend in Greece, 'Ecosystem modifications' including 'Dams and water management/use' and 'Other ecosystem modifications', affect as a whole 29 species (63%), having a medium/high impact for eight of them (27.6%). Agriculture was also a prominent threat, affecting 22 of the declining species (47.8%), 12 on a low scale and 10 on a medium/high scale. 'Pollution', 'Invasive species' and 'Hunting and collecting' threaten almost equal number of declining species (17, 17, and 16 respectively; Figure 2).

Trigger species in each of the 204 IBAs of Greece ranged from one to 25 (mean of 4.4 trigger species per IBA). Sites with the highest trigger species richness (> 20) are major Ramsar Wetlands of International Importance located in western and northern Greece (GR011, GR012, GR020, GR081). Seventy-one out of 204 IBAs (34.8%) are triggered by at least one declining species. IBAs with the highest number of declining species (6) include one wetland in Northern Greece (Lake Kerkini; GR020) and two forest/lowland areas in Evros (north-eastern Greece; GR004, GR005) that are deemed of European importance for birds of prey (Figure 3; Hallmann 1985; Poirazidis *et al.* 2011). The three most frequently recommended conservation actions across species decreasing in Greece were 'Land and water management', 'Species management' and 'Law and policy', and they mainly refer to raptors and wetland species. Research recommendations emphasized the need to further elucidate the potential threats that affect the species declining in Greece (Figure 4).

## Discussion

Our results indicate that almost one fifth of the breeding birds in Greece have declining populations. Among them, there are some cases where the population decline is well-documented such as

Figure 2. Number of species for which each threat class was listed for a) all species breeding in Greece and b) only for the species with decreasing trend. Threats are grouped by having low or medium/high impact.

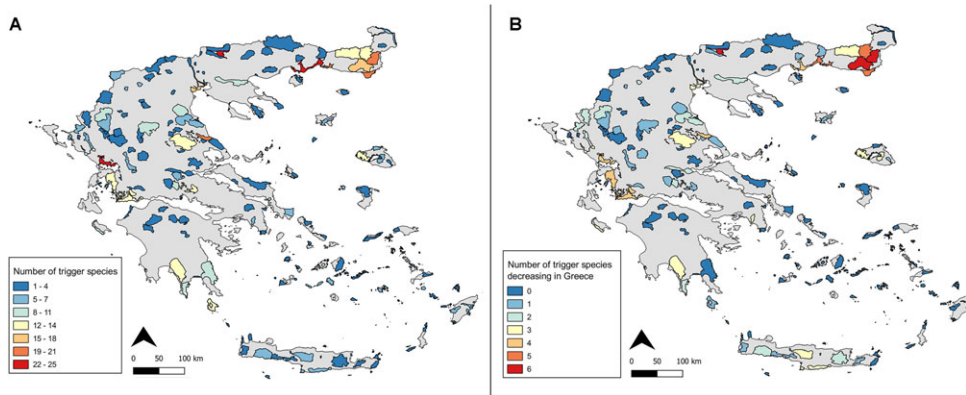

Figure 3. All 204 IBAs in Greece color coded according to a) trigger species richness and b) number of trigger species with decreasing trends.

the Whiskered Tern and Black Tern *Chlidonias niger*. Both species depend on floating vegetation for nesting (Paillisson *et al.* 2006) and have been breeding in Lake Kerkini, north-western Greece, benefitted from hydrological changes that resulted in the appearance of an extensive bed of white water lilies *Nymphaea alba* after 1982 (Crivelli *et al.* 1995). When the water lily bed almost disappeared (Manou and Papathanasiou 2009), the number of breeding pairs dropped almost to zero (Legakis and Maragou 2009). Moreover, the Egyptian Vulture population has suffered steep declines not only in Greece but throughout the Balkan Peninsula. In the last 30 years, the range of the species has decreased considerably and its populations have suffered a steep decrease of 80%, at an estimated rate of 4–8% per year (Veleviski *et al.* 2015), a value consistent with the rate of 3.9% we report in this study for the last 20 years. However, some other declines are much more challenging to interpret; some common passerine species such as the Chaffinch *Fringilla coelebs* and the Moustached and Great Reed warblers were found to show alarming rates of decline in the

Figure 4. Priorities for a) conservation actions and b) research recommended for the declining breeding birds of Greece as listed by IUCN.

country. Monitoring passerine populations requires long-term schemes and even then, estimations are susceptible to bias due to a variety of factors (Nichols *et al.* 2009). Thus, these results could very well be an artefact of the dataset heterogeneity (as mentioned in the methods section). However, it has been proposed that European common birds show rapid declines in contrast to less abundant ones (Inger *et al.* 2015) and therefore our results should be kept in mind as such species may be in need of special attention in the future. In fact, the trends of the two warbler species are considered overall stable in neighbouring countries (e.g. Bulgaria; Iankov 2007), however a suspected declining trend for the Great Reed Warbler has been indicated (Dyrz 2020). On the other hand, species showing the greatest increase include one that is regarded as invasive. The Collared Dove has progressively occupied almost all Greek territory since the beginning of the 20<sup>th</sup> century (Handrinos and Akriotis 1997), whilst such a pattern is documented throughout Europe with colonization of new areas (Hengeveld and Vandenbosch 1991) and even its expansion as an invasive species in North America (Sauer *et al.* 2017). Similarly, the Cattle Egret which was not breeding in Greece until 1991 (Goutner *et al.* 1991) has since showed remarkable increase in its population size. Such an expansion is reported from other areas too, e.g. from Italy (Nunes *et al.* 2010) and Algeria (Si Bachir *et al.* 2011). The Rook, which was considered a sporadic breeder in the country, showed a tremendous increase since 1992. Interestingly, similar patterns were observed in the UK, with an increase of 40% in 20 years (Marchant and Gregory 1999) and in Germany where the population of the species decreased substantially by 1976 and subsequently increased by 86.4% of its initial size until 2017, following the placement of the species' conservation status under protection in 1977 (Krüger *et al.* 2020). Finally, regarding the case of the European Storm-petrel *Hydrobates pelagicus*, the significant increase reported herein, reflects the intensified research efforts on seabirds that took place in Greece during the last decade and led to the discovery of new breeding colonies (Eric *et al.* 2012) or to more accurate estimates of known breeding. In fact, the species' trend in Europe is considered "Unknown" (BirdLife International 2015) further reflecting the uncertainty

in monitoring efforts of the species, and data on European Storm-petrel abundance should be treated with caution (de León *et al.* 2006).

When examining species at the taxonomic level, although our results showed no disproportionate declines between orders, they indicated that the breeding raptors of Greece constitute the most threatened group. This is further elucidated by the analysis of ecological traits and specifically the primary diet of each species, with scavengers being proportionally the most declining group of birds in Greece. The fact that raptor species in Greece are in decline was realised in the 1980s (Hallmann 1985) with the main causes including habitat loss and shooting. Today both these threats persist; shooting is the main cause of admission of raptors to wildlife rehabilitation centres (Mazaris *et al.* 2008) while habitat loss mostly relates to ongoing development plans and accompanying infrastructure, which can have a tremendous effect on raptor populations, especially if such plans are implemented inappropriately (Carrete *et al.* 2009, Vasilakis *et al.* 2017). Furthermore, additional threats become more and more evident. Currently, illegal poisoning is now considered as one of the leading threats to raptor species, threatening their populations at a national level (Ntemiri *et al.* 2018) and triggering scavenger declines and local extinctions throughout the country (Xirouchakis *et al.* 2001, Skartsi *et al.* 2008). Raptor declines are not limited to Greece but are currently a global phenomenon. Despite their value and role in providing critical ecosystem services (Gaston *et al.* 2018) this is the most threatened group of birds in the world (Buechley and Şekercioğlu 2016, McClure *et al.* 2018). This is rather alarming as top predators have been linked to higher levels of biodiversity and thus their preservation should be prioritized and enable ecosystem-level conservation and broader biodiversity benefits (Sergio *et al.* 2006).

According to IUCN Red List assessments, agriculture was identified as the most frequent threat for the breeding birds in Greece, both for all species and for species with declining trends. Population declines of farmland birds have become a major conservation concern throughout Europe (Tucker and Heath 1994, Gregory *et al.* 2004) and have been driven by land-use changes and agricultural intensification as enforced by the Common Agricultural Policy (CAP) (Donald *et al.* 2002, Busch *et al.* 2020). The severity of farmland bird declines is further reflected by a > 50% reduction of the EU farmland bird indicators since 1980 (Gregory *et al.* 2005, EBCC 2017). Although our results suggest that currently there are no disproportionate habitat-related declines regarding farmland birds in Greece, policies such as the CAP act at large spatial scales and can have tremendous impact on bird populations over extended geographic areas. Therefore, future implementation of management practices, to either prevent farmland bird declines or to restore agricultural landscapes, should largely focus on efficient tuning of the CAP and a possible reorientation towards environmental sustainability and thus effectively facilitate biodiversity conservation (Pe'er *et al.* 2019). Unsurprisingly, natural system modifications, including dams and water management as well as pollution (that encompasses discharges with fertilizer and pesticide residues), ranked among the most frequent threats and are mainly linked to abovementioned agricultural practices. The threat category "Hunting and collecting terrestrial animals" was the second most important threat identified in this study. We should note that species could actually be affected by a wide range of different threats encompassed in this category as it consists of heterogeneous threat types including intentional events for subsistence, sport or direct persecution along with any unintentional resulting mortality, such as poisoning. The category includes both legal and illegal hunting (Salafsky *et al.* 2008). Despite the obvious pressure that direct actions such as hunting/illegal hunting can have on both resident and migratory bird populations (Gross 2015), there are many subtle effects that are included in this category, such as lead poisoning. Poisoning from lead shot in waterfowl has been well documented (Mateo 2009) but there is increasing evidence that terrestrial species such as raptors and game birds are also affected by exposure to high levels of lead through spent hunting ammunition (Fisher *et al.* 2006). In Greece, lead ingestion by waterfowl has been documented since the 1990s (Pain and Handrinos 1990), whereas recently lead poisoning was found to be an additional pressure on the Egyptian Vulture (Bounas *et al.* 2016), a species that, as we have already mentioned, shows one of the sharpest rates of decline in the country and is listed as globally 'Endangered'. The threat posed by invasive species has a low impact

on most species but affects all seabirds in Greece. Invasive species, and specifically rats *Rattus spp.*, are believed to be one of the primary threats to nesting seabirds (Croxall *et al.* 2012) and global efforts on their eradication have proved to be substantially beneficial (Jones *et al.* 2016). In Greece, several actions on rat eradication have been implemented to safeguard seabird breeding grounds and have resulted to substantial conservation gains (Fric *et al.* 2012).

Given that threats causing habitat alteration and degradation are the most important for the breeding birds of Greece, "Land and Water Management" outranks the rest of the recommended conservation actions. However, except for restoring habitats and ecosystem functions, this category also encompasses the management of protected areas (Salafsky *et al.* 2008). Although wetland IBAs seem to hold the highest number of trigger species, contrastingly, the highest number of declining trigger species is observed in the lowland areas of Thrace, north-eastern Greece. This is rather unsurprising due to the fact that the Evros area is a stronghold for raptor populations and is characterised by one of the most diverse arrays of breeding raptor species in Europe (Hallmann 1985, Poirazidis *et al.* 2011). Therefore, adequate protection of such areas of international importance is necessary and development plans that could lead to habitat loss and degradation should be discouraged. In addition, priority conservation actions should be implemented in order to safeguard the future of raptor populations. Given the threat posed to raptors by poisoning, it is logical that the most frequently recommended conservation actions within Red List assessments for the breeding birds of Greece are "Species management", "Education and Awareness" as well as development and enforcement regarding "Law and Policy". Improvement of legislation is the action that currently could most likely make a difference; law enforcement and the establishment of a clear legal framework laying out the responsibilities of authorities involved is a priority issue in order to tackle the illegal use of poison bait in Greece (Ntemiri *et al.* 2018). Improved regulation regarding the use of poisons and lead ammunition, mitigation of the risk of electrocution/collision on dangerous powerlines, and the sensible spatial planning of wind farms to minimize conservation costs (Vasilakis *et al.* 2017), could help prevent the accelerated anthropogenic mortality of bird species.

To be efficient, conservation actions they need to be informed by further research. Our results suggest that specific drivers of change have to be identified along with examination of current and past population trends. Indeed, ornithological research in Greece since the 1980s has focused on the increase of knowledge regarding the distribution, numbers and status of many bird species as well as their breeding ecology. However, studies that deal with population monitoring and effects of different factors on bird populations were rather rare in the past although they have recently been increasing (Kazantzidis 2007). Standardized bird monitoring efforts can subsequently lead to a more rapid response in addressing any drivers of population decline and thus further increase the strength and accuracy of Red List Assessments. Eleven years have passed since the publication of the Red Data Book of Greece (Legakis and Maragou 2009), and this study further corroborates the imperative need to update the Red Data Book and include more species in its assessments, especially of breeding species for which the country bears the greatest responsibility.
