

TERRESTRIAL BIOTA CHECKLIST OF THE CHINIJO ARCHIPELAGO AND LOBOS (CANARY ISLANDS)

José María Fernández-Palacios*, Zaira Negrín, Silvia Fernández Lugo,
José Ramón Arévalo & Lea de Nascimento

ABSTRACT

A new checklist of the terrestrial biota from the easternmost islets from Canary Islands (Roque del Este, Roque del Oeste, Montaña Clara, Alegranza, La Graciosa and Lobos) is provided as a result of a wide bibliographic and database compilation. The checklist includes bryophytes, vascular plants, fungi, chordates, arthropods and mollusks. Additionally, a short analysis of the fauna and flora species richness reveals that there are slightly more than 700 terrestrial species in the islets, the big majority of them being native, with > 25% endemics and < 10% exotics, what argues in favour of the high conservation quality of this protected area. By far, the more important taxa contributing to this biodiversity are arthropods and vascular plants, as happen in the rest of the archipelago. Up to seven different taxa, four spiders, one bird –already extinct–, one snail and one vascular plant, have been found to be endemic to the islets. Finally, the availability of this new checklist will contribute significantly towards more accurate biogeographic analyses of the Canarian biota, because until now the islets' biota distribution was not disaggregated of the main islands, Lanzarote and Fuerteventura, to which politically belong.

KEYWORDS: biogeographical analysis, compilation, species distribution, terrestrial biota.

LISTADO DE LA BIOTA TERRESTRE DEL ARCHIPIÉLAGO CHINIJO Y LOBOS (ISLAS CANARIAS)

RESUMEN

Se presenta un nuevo listado de la biota terrestre de las isletas más orientales del archipiélago canario (Roque del Este, Roque del Oeste, Montaña Clara, Alegranza, La Graciosa y Lobos) resultado de una exhaustiva recopilación bibliográfica y de bases de datos. El listado incluye briófitos, plantas vasculares, hongos, cordados, artrópodos y moluscos. Un breve análisis estadístico de la flora y fauna de los islotes revela que existen algo más de 700 especies en el conjunto de los mismos, la gran mayoría de ellas nativas, con más de un 25% de endemismos y menos de un 10% de especies exóticas, lo que avala la alta calidad de estos espacios protegidos. Con diferencia los taxa que más contribuyen a la biodiversidad inventariada son los artrópodos y las plantas vasculares, como ocurre en el resto del archipiélago. Hasta siete taxones diferentes, cuatro especies de araña, un ave –ya extinta–, un molusco y una planta vascular, son endémicos de estas isletas. La disponibilidad de esta lista contribuirá a la realización de análisis biogeográficos más rigurosos, pues hasta ahora la biota de las isletas no se encontraba desagregada de las islas mayores, Lanzarote y Fuerteventura, a las que pertenecen políticamente.

PALABRAS CLAVE: análisis biogeográfico, compilación, distribución de especies, biota terrestre.

Figure 1. Geographical location of the islets considered in this study.

Despite the outstanding contribution that the existing species checklists of the NE Atlantic archipelagos (Arechavaleta *et al.* 2005, 2010; Borges *et al.* 2008, 2010) have provided for the recent progress of Macaronesian biogeography in particular and island biogeography in general (Emerson and Kolm, 2005; Whittaker *et al.* 2008; Rijsdijk *et al.* 2014; etc.), the Canarian checklist (Arechavaleta *et al.* 2010) is still counting with an important bias. This is that the species distribution information of the islets belonging to the so-called Archipiélago Chinijo (north to Lanzarote), comprising Roque del Este, Roque del Oeste, Montaña Clara, Alegranza and La Graciosa), as well as the information of Lobos islet, north to Fuerteventura (fig. 1), has been aggregated respectively within Lanzarote and Fuerteventura. Actually all these islets were, together their main respective islands, part of the Pleistocene island called Mahan, which extended in the Last Glacial Maximum (ca. 18 Ky BP) for more than 5000 km² (Fernández-Palacios *et al.* 2011), but have became different insular entities at least ca. 15 Ky BP, during the last deglaciation.

* Departamento de Botánica, Ecología y Fisiología Vegetal, Universidad de La Laguna, La Laguna, 38205, Tenerife, Spain. Corresponding autor: jmfperal@gmail.com.

Contrastingly, other Macaronesian archipelagos' checklists, provide information about the islets species distribution to a large extent disaggregated from their respective main islands. For instance, Cape Verde checklist separates the information of the islets of Branco and Raso, close to Santa Luzia and São Nicolau, from these two islands, although this is not the case for Rombos islet, which is included within Brava (Arechavaleta *et al.* 2005). On the other hand, Madeira checklist disaggregates the information from Desertas and Salvajes archipelagos, although not of the islets included within them (Deserta Grande, Bugio and Ilheu Chao in Desertas and Selvagem Grande, Selvagem Pequena and Ilheu de Fora in Selvagens, respectively) (Borges *et al.* 2008). Finally, Azores disaggregates Corvo information from Flores (Borges *et al.* 2010), but there is no entrance for Formigas, a tiny islet halfway between Santa Maria and São Miguel. Remarkably, all those islets with disaggregated information are smaller than La Graciosa, and, with the exception of Corvo, than Alegranza or Lobos.

Some consequences of this lack of disaggregation for islets species distribution are, for instance, that the Canarian checklist includes islets endemic taxa attributed either to Fuerteventura or to Lanzarote. These errors cause loss of information and precision, generating inaccurate lists and thus, results and interpretations. Furthermore, counting with the islets' checklist biogeographic analyses could be performed with 11 (not including rocks) or even 13 (including the rocks) items and not only with seven, as used to happen today, where El Hierro (270 km^2) is considered the smallest island. With the new checklist the island area range will be incremented in several orders of magnitude.

Thus, our aim in this study is to generate a new, updated checklist of the terrestrial biota from Chinijo's archipelago and Lobo's islet through a wide bibliographical and database compilation of all the terrestrial flora and fauna been described for these areas.

The checklist is based on published or unpublished information obtained from different sources either for their vascular flora (Kunkel, 1970, 1971; Marrero, 1991), fungi (León Arencibia *et al.* 1991; Beltrán-Tejera *et al.* 1998; Bordallo *et al.* 2012; Chávez-Barreto *et al.* 2016), vertebrate fauna (Martín and Lorenzo, 2001; Martín *et al.* 2003; Rodríguez *et al.* 2003; Lorenzo, 2007; Siverio *et al.* 2009; Ramírez *et al.* 2014), invertebrate fauna (Oromí and Arechavaleta, 1995; Pérez *et al.* 2003; Oromí *et al.* 2003; Macías *et al.* 2004), general approaches about specific islets, such as La Graciosa (González Viera *et al.* 1996), Montaña Clara (Wildpret *et al.* 1997; Varios autores, 2006) or Lobos (Romero, 2017), and finally personal communications (such as Prof. González Mancebo for bryophytes or Prof. Oromí for invertebrates). Although Kunkel (1970, 1971) included cultivated (garden, agriculture, plantations) species, either growing wild or not, in this checklist cultivated species growing wild have been included as exotics, while those not growing wild have been excluded.

Species have been listed according to their presence (+), absence (-) or data inexistence (*) in the different islets analysed: Roque del Este (RE), Roque del Oeste (RO), Montaña Clara (MC), Alegranza (AL), La Graciosa (LG) and Lobos (LO). Following the Canarian checklist procedure (Arechavaleta *et al.* 2010), for each

taxon its origin (Or) [secure native (NS), likely native (NP), possible native (NO), likely introduced (IP), non-invasive secure introduced (IS) and invasive introduced (II)] and endemicity status (En) [endemics subspecies (ESS), endemic species (ES), endemics genus (EG) or islet endemic (IE)] are given. Information about extirpated or extinguished taxa (e) or with doubtful presence (?) is also included. When for a specific species only doubtful presences are referred along the study area, the species has been omitted from the list. By contrast, if there is at least one confirmed presence (+) along the study area, doubtful presences are considered. Species and the families to whom they belong have been listed according to alphabetic order within taxonomic phyla.

As was to be expected, the survey effort has not been the same all over the islets studied, so that for instance, vascular plants have been especially well studied for Lobos, and the arthropod fauna for Montaña Clara. The two larger islets (La Graciosa and Alegranza) have received intermediate sampling efforts and finally, due to their inaccessibility the sampling effort for the tiny rocks has been very limited. Thus, the species list is simultaneously a trade off of the islets true diversity on the one hand, and on the inventory effort on the other, as seems to happen universally (Hortal *et al.* 2007). Even so, we consider the resulting checklist (see appendix) as a first step towards the disaggregation of the islets dataset and thus a real basis for biogeographic analyses improvement.

The checklist includes six taxonomic groups: bryophytes, vascular plants, arthropods, mollusks, chordates and fungi. Unfortunately, we have not been able to find sources for lichen distributions in those islets, although it is known that there exist some (Varios autores, 2006).

On the other hand, aiming completeness, the checklist has included species that have been extinct (such as the malpaís mouse *Malpaisomys insularis*, the black oystercatcher *Haematopus meadewaldoi* or the endemic Chinijo archipelago stonechat *Saxicola dacotiae* ssp. *murielae*) or extirpated (such as the Egyptian vulture *Neophron percnopterus* or the osprey *Pandion haliaetus*) in historical times from all or some of the islets.

For the statistical analysis we have consider extinct or extirpated taxa (*e* in the checklist, see appendix) as species presence (+), whereas doubtful presence (?) in the checklist) or no data (*) in the checklist) was precautionary consider as species absence.

704 different terrestrial species have been found growing on the islets (see appendix), although we believe that there should be more because the impossibility of finding lichen and other invertebrate information further than arthropods or mollusks species. Leaving apart the two very tiny rocks, Roques del Este y del Oeste, with 33 and 16 species respectively, the species richness of the different islets is remarkably similar, around 300 species, despite their very different area, varying from 1.33 km² (Montaña Clara) to 27.3 km² (La Graciosa) (table 1). Within the species present, from a chorological perspective the non-endemic native element is by far the more abundant (varying from 75 to 49% among the different islets), followed by the endemic species (shifting from 45 to 25%) and finally, by the introduced species, always < 10% and almost absent of the rocks. The very low contribution of

the exotic species all over the studied phyla on the islet diversity argues in favour of the high conservation status of this natural area (table 2).

TABLE 1. GEOGRAPHICAL DATA OF THE ISLETS STUDIED

| ISLET | AREA (km ²) | ALTITUDE (m) | CLOSEST MAIN ISLAND | DISTANCE TO THE MAIN ISLAND (km) | 2017 HUMAN POPULATION |
|-----------------|-------------------------|--------------|---------------------|----------------------------------|-----------------------|
| La Graciosa | 27.3 | 266 | Lanzarote | 1.15 | 721 |
| Alegranza | 10.2 | 289 | Lanzarote | 16.56 | - |
| Montaña Clara | 1.33 | 256 | Lanzarote | 8.39 | - |
| Roque del Este | 0.06 | 86 | Lanzarote | 10.96 | - |
| Roque del Oeste | 0.01 | 43 | Lanzarote | 9.79 | - |
| Isla de Lobos | 4.58 | 122 | Fuerteventura | 1.95 | 4 |

TABLE 2. NUMBER OF SPECIES AND PERCENTAGE OVER THE TOTAL ISLET RICHNESS IN BRACKETS, ACCORDING TO ITS BIOGEOGRAPHICAL ORIGIN

| CHOROLOGICAL STATUS | ROQUE DEL ESTE | ROQUE DEL OESTE | MONTAÑA CLARA | ALEGRAZNA | LA GRACIOSA | ISLA DE LOBOS | TOTAL |
|------------------------|----------------|-----------------|----------------|----------------|----------------|----------------|----------------|
| Endemic sp. | 15 (45.4%) | 4 (25%) | 96 (31.9%) | 81 (26.4%) | 84 (26.9%) | 74 (24.7%) | 222 (31.4%) |
| Non-endemic native sp. | 16 (48.5%) | 12 (75%) | 194 (64.5%) | 212 (69.1%) | 198 (64.3%) | 194 (65.8%) | 418 (59.5%) |
| Exotic sp. | 2 (6.1%) | 0 (-) | 11 (3.6%) | 14 (4.6%) | 27 (8.8%) | 28 (9.5%) | 64 (9.1%) |
| Total sp. | 33 | 16 | 301 | 307 | 309 | 296 | 704 |

In respect to the contribution of the different taxonomic groups to the island biodiversity, arthropods and vascular plants are the more abundant groups with > 90% of the species present, whereas the rest only account for an 8% of the species richness (table 3). Interestingly there are two exclusive taxa shared by Montaña Clara and Alegranza, the (already extinct) passerine landbird (*Saxicola dacotiae* ssp. *murielae*) and the spider *Salticus alegranzaensis*; four more are exclusive from Alegranza, the spiders *Cerbalus alegranzaensis*, *Dysdera alegranzaensis* and *Eurypoena tuberosa* ssp. *alegranzaensis*, and the snail *Cryptella alegranzae*; and finally, one vascular plant, *Limonium ovalifolium* ssp. *canariensis*, exists exclusively in Lobos. No exclusive species has been reported for La Graciosa, neither for the Roques so far.

Summarizing we present here a new biogeographical tool, that even needing some improvement and refinements as the incorporation of new taxonomic groups (such as the lichens), constitutes a significant step towards counting with a species checklist for the complete Canarian archipelago.

TABLE 3. SPECIES DISTRIBUTION AND PERCENTAGE OVER THE TOTAL ISLET BIOTA IN BRACKETS OF THE DIFFERENT TAXONOMIC GROUPS PER ISLET

| TAXA | ROQUE DEL ESTE | ROQUE DEL OESTE | MONTAÑA CLARA | ALEGREZA | LA GRACIOSA | ISLA DE LOBOS | TOTAL |
|--------------------|-------------------|--------------------|------------------|----------------|----------------|------------------|----------------|
| Arthropods | 13 (39.4%) | * | 171 (56.8%) | 142 (46.2%) | 110 (35.7%) | 96 (32.5%) | 390 (55.5%) |
| Mollusks | 1 (3%) | * | 6 (2.0%) | 5 (1.6%) | 1 (0.3%) | 3 (1%) | 10 (1.4%) |
| Birds | 7 (21.2%) | 8 (50%) | 19 (6.3%) | 24 (7.8%) | 22 (7.1%) | 22 (7.4%) | 33 (4.7%) |
| Reptiles | 2 (6%) | 2 (12.5%) | 2 (0.6%) | 2 (0.6%) | 2 (0.7%) | 3 (1%) | 3 (0.4%) |
| Mammals | 0 (-) | 0 (-) | 1 (0.3%) | 2 (0.6%) | 4 (1.4%) | 4 (1.4%) | 5 (0.6%) |
| Bryophytes | 0 (-) | 0 (-) | 2 (0.6%) | 6 (1.8%) | 4 (1.3%) | 7 (2.3%) | 11 (1.6%) |
| Fungi | 0 (-) | 0 (-) | 0 (-) | 2 (0.6%) | 4 (1.3%) | 3 (1%) | 8 (1.1%) |
| Vascular plants | 10 (30.3%) | 6 (37.5%) | 100 (33.2%) | 124 (40.4%) | 162 (52.6%) | 158 (53.6%) | 244 (34.7%) |
| TOTAL | 33 | 16 | 301 | 307 | 309 | 296 | 704 |

RECIBIDO: octubre de 2017, ACEPTADO: noviembre de 2018

ACKNOWLEDGMENTS

The authors are very grateful with our Department colleagues Professors Juana María González Mancebo and Esperanza Beltrán Tejera for facilitating information concerning the distribution of bryophytes and fungi. Prof. Dr. Pedro Oromí (Zoology Department) provided us unpublished data of invertebrate distribution in the islets. Finally, two anonymous referees contributed to the improvement of this manuscript.
